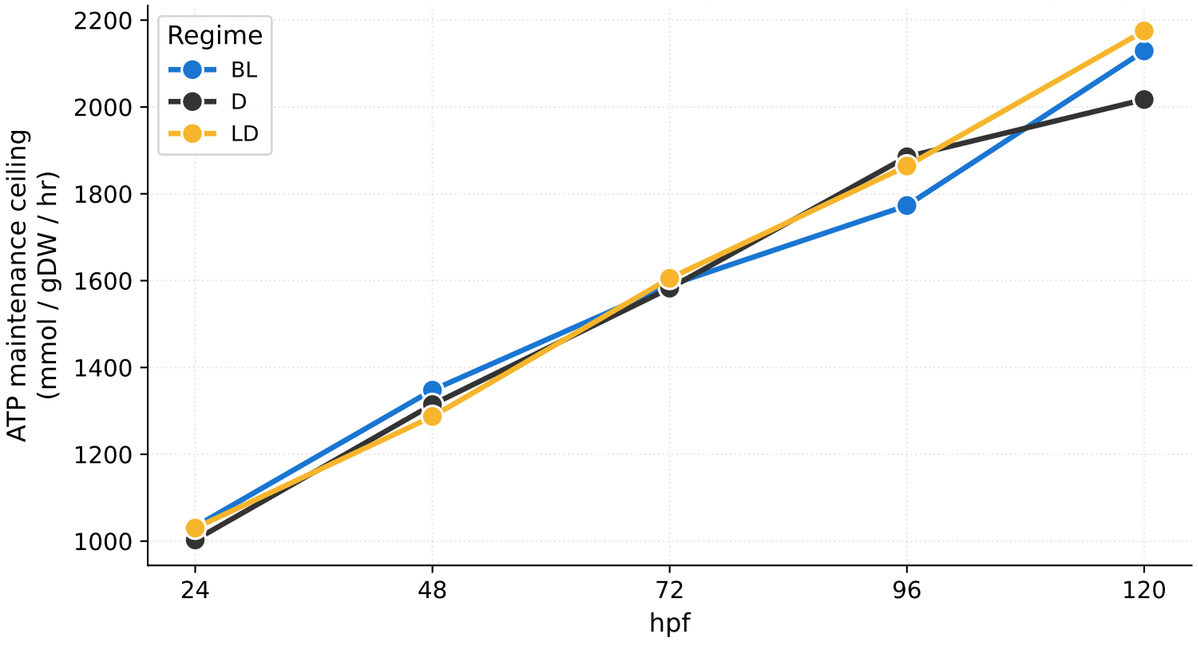
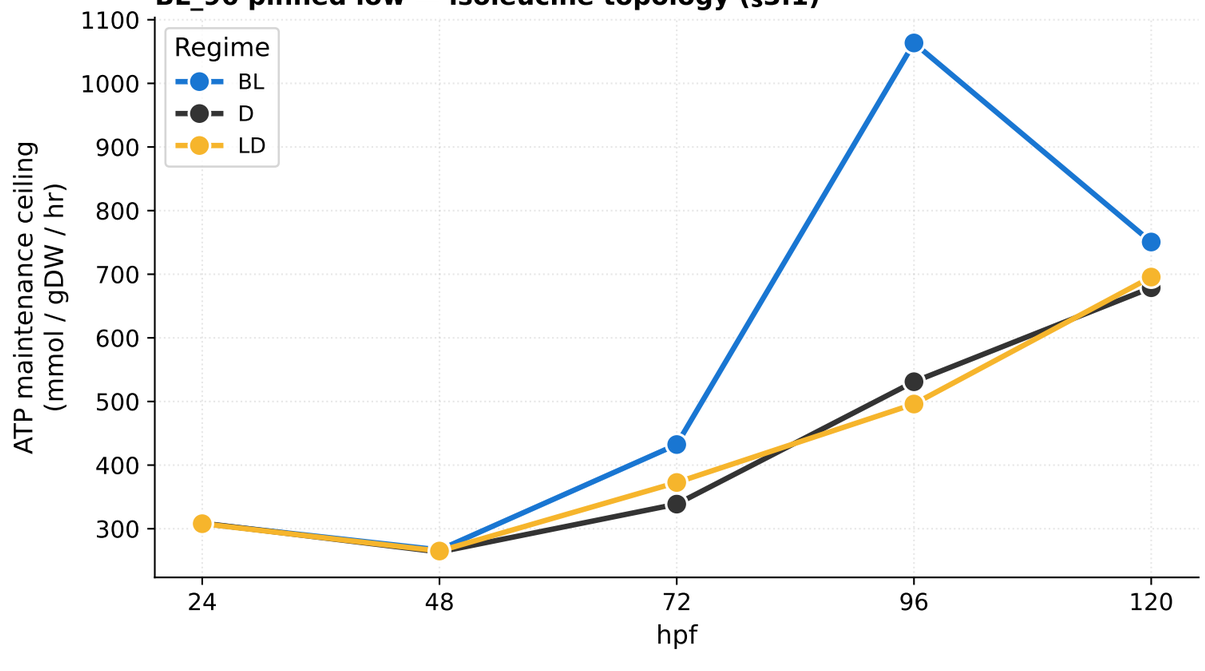
Figure C — ATP capacity probe: bulk energetic capacity is set by developmental stage, not by light history

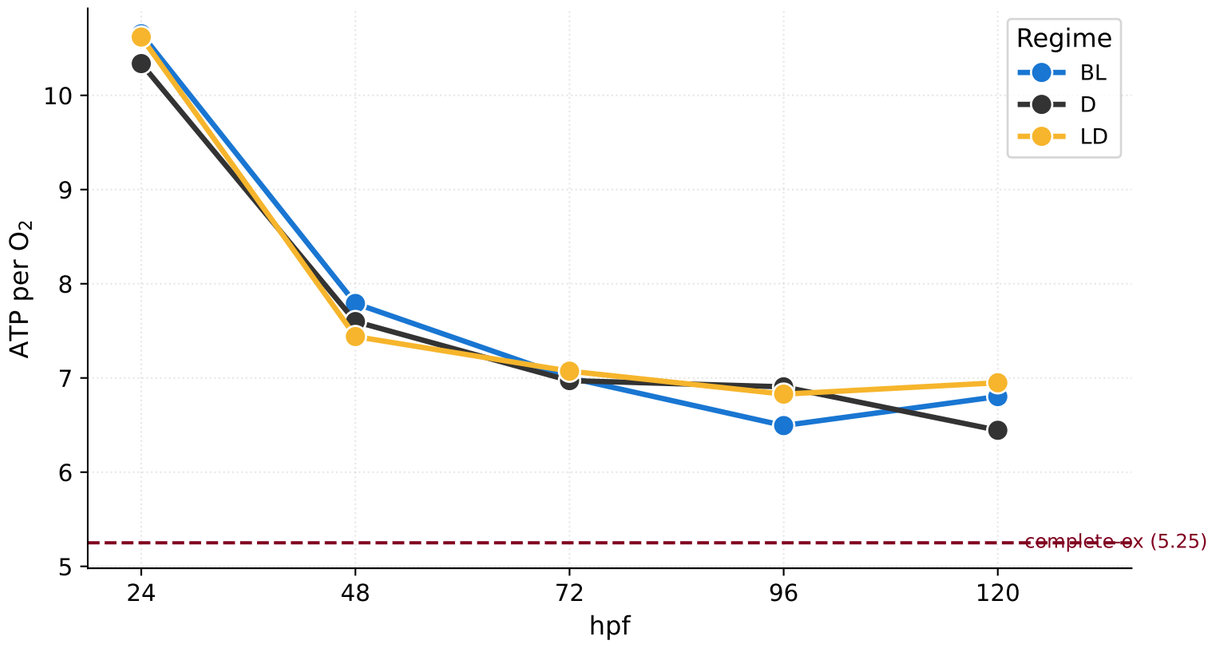
A Free-biomass ATP ceiling
2.1× rise 24→120 against 3.2× cap; regimes within 8% at every stage

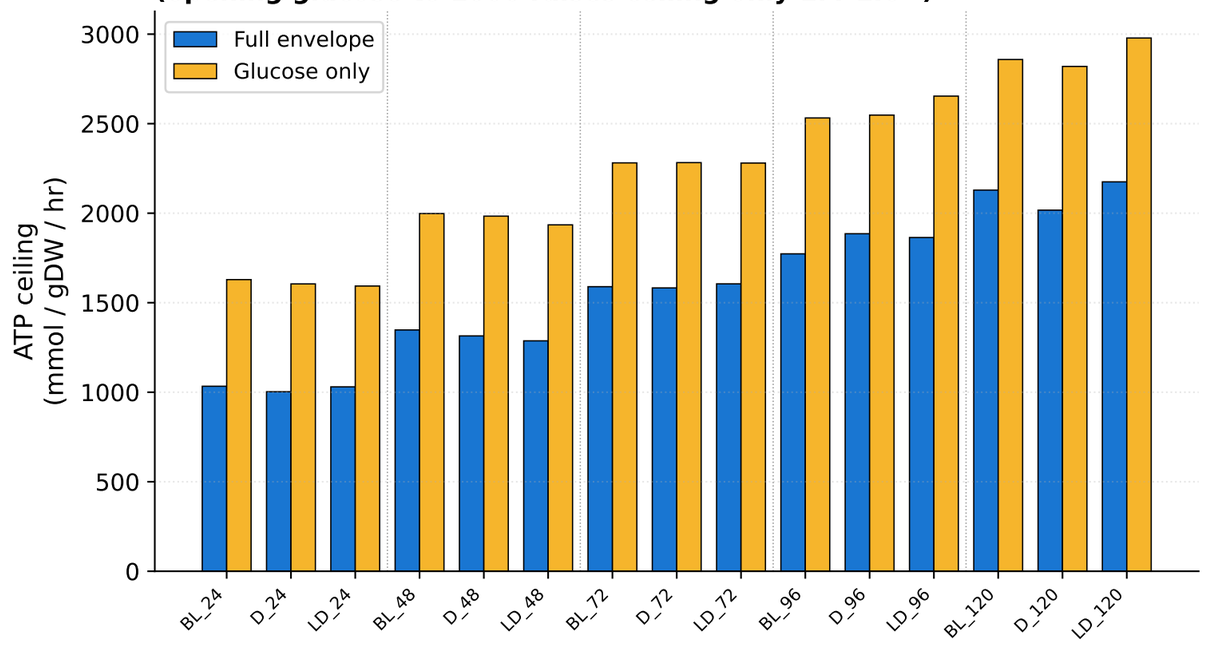


B Per-cell biomass floor (0.9 × biomass_max)
BL_96 pinned low — isoleucine topology (§3.1)



C ATP per O_2 falls — non-oxidative share shrinks with development





D Glucose-only control — oxygen, not substrate, sets the ceiling
(opening glucose to 1000 raises ceiling only 1.4-1.6×)
